To complete this project, each team member was assigned different parts to work on.

Muhammad Faizzuddin Bin Mohd Nazli - System Design and Logic Implementation

He was the one who planned how the whole system should work. He created the main design of the system and decided how each part should connect with each other. He also did the coding for the system logic that control how data move between different parts. Besides that, Faiz handled the setup of user interface using special libraries like Guna UI2 and Krypton Toolkit, so the design looks clean and modern.

Lew Wei Cheng – Sales Module and Functional Interface

He worked on everything related to sales. He built the sales form where users can record sales, input customer orders and process transactions. He made sure this part works together with the stock system, so when items are sold, the stock updates correctly. Wei CHENG also helped make the interface easy to use for this section.

Namunesswaran A/L Siva Perumal – Product Management Module

He focused on the product management part of the system. He created the forms and logic that let users add new products, edit product details and assign them to categories. He also handled the connection between product information and stock control, so when something is changed, it will show up properly in the system. Namu made sure the product data is saved and shown correctly in the product list.

Muhammad Luqman Hakim Bin Mohamad 'Asri – Reporting and Data Visualization

His job was to handle reports. He created the parts where users can view sales, inventory and stock summaries. He also made sure the reports are easy to read and clear to understand. He worked on the format and how the data should be shown in a simple way for the users.

DESCRIPTION OF THE PROJECT

This project is a Windows Forms-based Inventory Management System developed using C# in Visual Studio 2022. It is designed for small to medium-sized businesses to efficiently manage products, inventory stock levels, transactions, and sales. The application features a modular, multi-form architecture and uses Firebase Realtime Database for cloud-based storage and data synchronization.

Core Functionalities:

1. Dashboard Navigation:

- Central control panel (frmDashboard) with navigation to submodules.
- Panel loading system that opens each child form (frmHome, frmInventory, etc.) inside a container panel.

2. Product Management:

- Add, update, and delete products.
- Each product includes a unique ProductID, category, supplier, quantity, and price.
- Category management using a list class and UI integration.

3. Inventory Control:

- Manual stock adjustments and automated updates based on transactions.
- Low-stock detection and real-time updates to Firebase.

4. Transaction Management:

- Entry of 'Stock In' and 'Sale' transactions via frmTransactionEntry.
- Transaction filtering by type, date, category, and supplier.
- Auto-generated reference numbers and real-time total amount calculation.

5. Sales and Reporting:

- Sales tracking and revenue computation.
- Dynamic report generation for sales and stock, saved under a unified Reports node.
- Integration of polymorphic Report, SalesReport, and StockReport classes with Firebase.

6. Home Dashboard (frmHome):

- Real-time statistics display using lblProduct, lblTransactions, and lblSales labels.

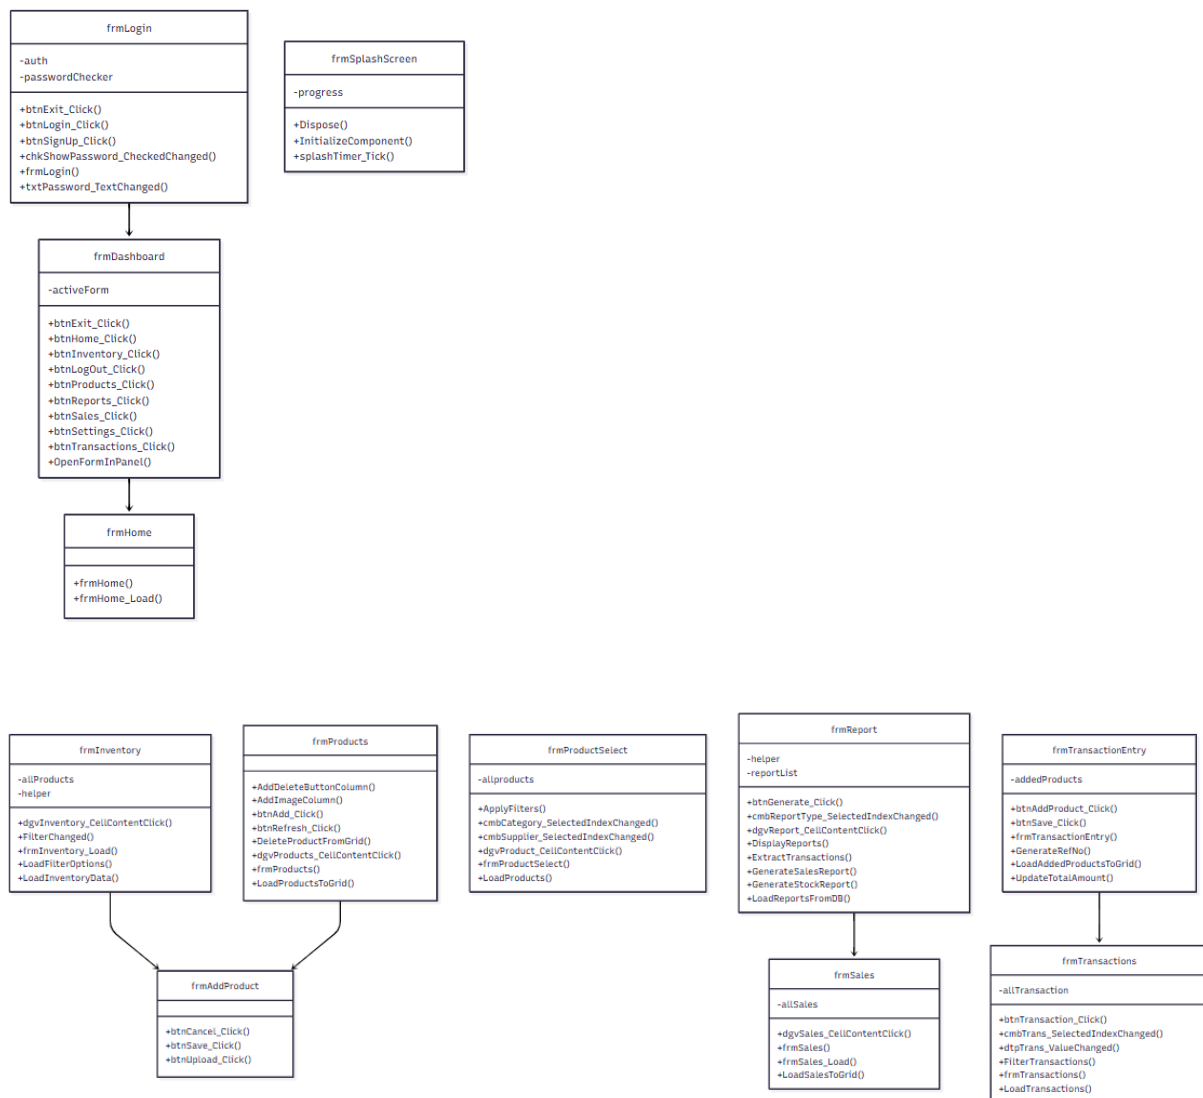

- Data retrieved directly from Firebase using helper methods (GetProductCount(), etc.).

7. Authentication and Navigation:

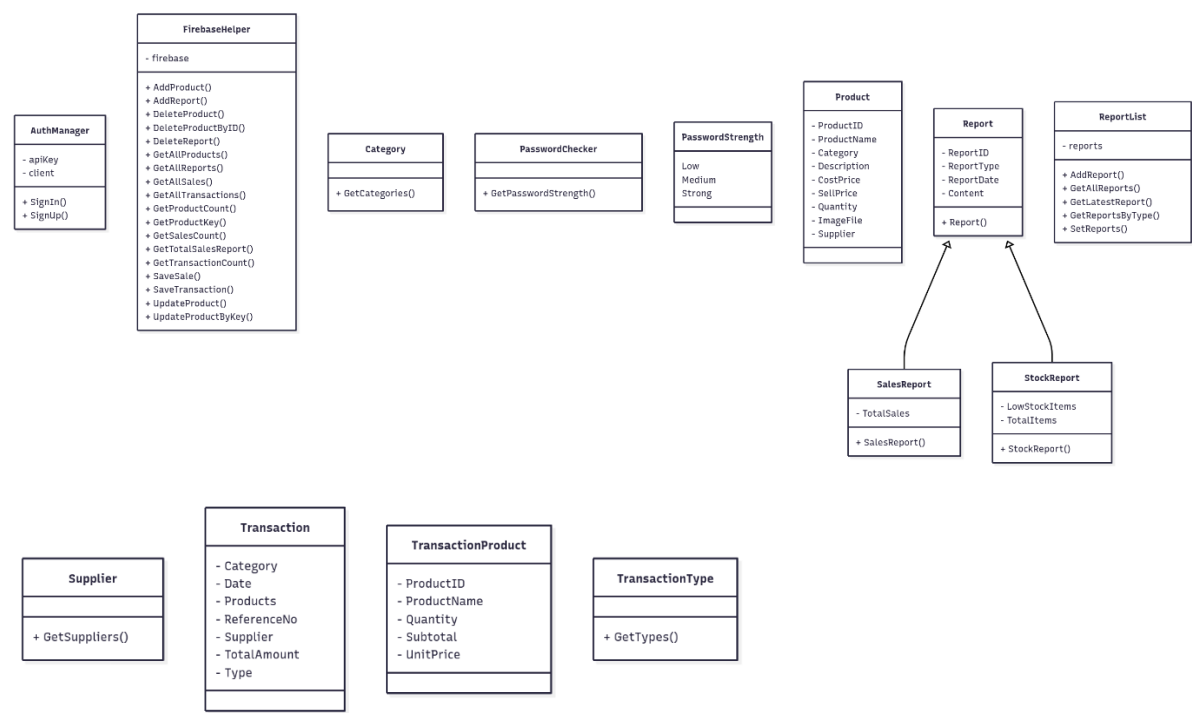

- Login system integration (via frmLogin) with session redirection upon exit or logout.
